

***** PROJECT-2 *****

STEPS TO BE FOLLOWED

Step-1: VPC has public subnets and private subnets in the two availability zones

Step-2: Each public subnet contains a NAT gateway and load balancer node

Step-3: The servers run in this private subnets are launched and terminated by using an autoscaling group, and rewrite traffic from the load balancer

Step-4: the servers can connect to the internet by using the NAT gateway

IMPLEMENTATION STRATS

CREATING VPC

Step-1: VPC or more

Step-2: Name for vpc

Step-3: No IPv6 CIDR block

Step-4: availability zones — (2)

Step-5: Public subnets of private (2)

Step-6: NAT gateways (1 per zone)

Step-7: VPC end points (none)

Step-8: create VPC

Elastic ip —> static doesn't change

NAT gateway —> it will mask the private ip address (instances) with the public ip of NAT gateway

NAT gateway —> took time for activation

Check created vpc — correct or not

MODULE-2 :CREATE AUTO SCALING GROUP

SEARCH EC2 — > THEN FIND AUTO-SCALING ON SIDE BAR

You cannot create autoscaling group directly

You can use launch templates

To know behaviour

First create launch templates

1. Templates name
2. Description
3. OS system (AMI)
 1. 4.Instance type (t3.micro)
5. Key value pair (create new)
6. Create new security group
7. None
8. Description
- 9.select VPC (create already)
10. Inbound rule —> * custom tcp/8000 all traffic anywhere
 * SSH 22 anywhere
11. Create launch templates

Go back to Acts- Sally Jours

- 1) Name
- 2) select launch torrtali - Next
- 3) Schoot, SPc (Creates one)
- 4) Avalability zonej (select Private 1, Porale 2)
- 5) Next
- 6) No load balancer
- 7) Next

8) Desired Capacity Cohort-2

Min -2

Max - 4

a). Scaling Policy — None - Next

10) Add Notification - Not

11) launch configuration

Check the EC2 Instance

check where subnets are created

Private 1, 2 correct or not

Module--3

Installing app on subnets

How to login ?

we don't have Public IP right?

So, here Comes our Bastion Host / Jump Server

Mediator basis Private subnet

& Public Subnet

Creating Bastion Host

Go to EC2 Instances

1) Create (launch EC2 Instance)

1) Name

2) Ubuntu

3) t3. micro

4) Key Pair

5) create security group

SSH from Public to SSH to private

install app

Select Allow SSH Traffic from Any where

6) Network setting -EDIT

- select VPC (creator one)

- Subnet Selection to [Public]

- Enable Auto- assign [IP]✓

Launch Instance

From beyton to SSH---- Poivali Subnet SSH

You will need key-Value Pair to SSH

Cory Key -Value Pais to Bastion Host

will use Shell Command (SCP Secure Copy)

open Mobex team

start local toominal

We Don't Need(SCP)

Method-1 Mobaxtorm graphical apay

1)Open Mobaxterm

2)New session

3)Remote host (bastian host) IPv4 public

4)Ubuntu

5) Schet Key-value pair

OK
